musician-father. The coefficient estimates indicate that while male and female composers were equally likely to have musician-fathers, female composers were a statistically significant 6 percentage points more likely to have musician-mothers than male composers. Given that only 3 percent of male composers had composer-mother, female composers were three times more likely to have a musician-mother than male composers. Musician-mothers may therefore have been especially important in nurturing female musical talent.

We next turn to the consequences of musician-parents for composer prominence. To do this, we estimate the following regression:

$$\begin{aligned} \ln(\text{word count})_i = & \beta_0 + \beta_1(\text{female})_i + \beta_2(\text{mother musician}) + \\ & \beta_3(\text{father musician})_i + \beta_4(\text{female})_i \times (\text{mother musician})_i + (3) \\ & \beta_5(\text{female})_i \times (\text{father musician})_i + \gamma_i + \delta_t + \varepsilon_i \end{aligned}$$

The outcome variable in this equation is the natural logarithm of the word count of composer i 's main description; female_i is a binary indicator equal to one if composer i is female; mother musician_i and father musician_i are binary indicators equal to one if composer i has a musician-mother or musician-father, and the remaining variables are defined as before. If musician-parents are beneficial for a composer's future prominence, β_2 or β_3 should be positive
